- [3 Memory expansion](#)

Summary

The **Memory expansion** function provides the possibility to expand the device's flash memory with a USB mass storage device.

This chapter of the user manual provides an overview of the Storage Memory Expansion page for {{{name}}} devices.

Prerequisites

To be eligible for router memory expansion, the USBMSD must qualify the following imposed restrictions:

- The USB must be the first one inserted. (For example, if you are using a USB hub, the eligible device is the first USBMSD attached to the hub.)
- The first partition of the USBMSD must be the primary partition.
- The size of the first primary partition must be at least 512 MB.
- The filesystem of the first primary partition must be ext2.

Take serious notice of the warnings displayed in the Memory expansion page. Here's what you need to know **before enabling memory expansion**:

- Memory expansion procedure will reboot the router.
- When reversing the memory expansion procedure, the router will be reverted to the state it was before the procedure. Make sure to fully configure the router before the procedure.
- The procedure will erase all existing files from the USBMSD.

- Samba shared directories on /mnt/sda1 will be deleted.
-

Here's what you need to know **before disabling memory expansion**:

- Disabling memory expansion will reboot the router.
- Disabling memory expansion will revert the router to the state it was before the memory expansion. This may leave router unconfigured if it was so before the expansion.
- Do not unplug the USBMSD before disabling memory expansion.

Memory expansion

It is highly recommended that you read the [Prerequisites](#) section or read the notes and warnings displayed in the WebUI page before enabling memory expansion.

If you insert a drive of a wrong format (not ext2), you will see a warning message like this:

If there is no drive inserted or there is another problem with the drive, you will see a warning message like this:

If everything is correct, simply enable memory expansion. save changes and wait for the router to reboot.

You can later check the router's memory state with the Linux *df* command or via the System widget in the Status → [Overview](#) page:
